

STAT151A Quiz 5 (Apr 23rd)

Please write your full name and email address:

The OLS estimator is given by $\hat{\beta} = (\mathbf{X}^\top \mathbf{X})^{-1} \mathbf{X}^\top \mathbf{Y}$.

You have 20 minutes for this quiz.

There are three parts, (a), (b), and (c), each weighted equally..

This quiz will use some facts about the standard normal distribution. If $z \sim \mathcal{N}(0, 1)$, then:

- $\mathbb{E}[z] = 0$
- $\mathbb{E}[z^2] = 1$
- $\mathbb{E}[z^3] = 0$
- $\mathbb{E}[z^4] = 3$

Recall that the OLS estimator of $y_n \sim \beta^\top \mathbf{x}_n$ is $\hat{\beta} = (\mathbf{X}^\top \mathbf{X})^{-1} \mathbf{X}^\top \mathbf{Y}$.

For this quiz, we will take

$$a_n \sim \mathcal{N}(0, 1) \text{ IID} \quad \text{and} \quad b_n = a_n^2.$$

Note that the pairs (a_n, b_n) are IID, but a_n and b_n are not independent.

Let $\mathbf{x}_n = (a_n, b_n)^\top$. Let $\boldsymbol{\beta} = (\beta_a, \beta_b)^\top$. Let $y_n = \boldsymbol{\beta}^\top \mathbf{x}_n + \varepsilon_n$, where ε_n are IID with $\mathbb{E}[\varepsilon_n] = 0$ and $\text{Var}(\varepsilon_n) < \infty$. The residuals ε_n and a_n are all independent of one another.

Note that a_n , b_n , β_a , and β_b are all scalars, and both \mathbf{x}_n and $\boldsymbol{\beta}$ are 2-vectors.

Let $\hat{\boldsymbol{\beta}}$ denote the OLS estimator of $y_n \sim \boldsymbol{\beta}^\top \mathbf{x}_n$, that is, of y_n regressed on both a_n and b_n . **Note that the regression for $\hat{\boldsymbol{\beta}}$ does not include a constant.**

Let $\hat{\alpha}$ denote the OLS estimator of $y_n \sim \alpha a_n$, that is, of y_n regressed on a_n alone. **Note that the regression for $\hat{\alpha}$ does not include a constant, and does not include b_n .**

(a)

Prove that, as $N \rightarrow \infty$,

- $\hat{\alpha} \rightarrow \beta_a$ and
- $\hat{\boldsymbol{\beta}} \rightarrow \boldsymbol{\beta} = \begin{pmatrix} \beta_a \\ \beta_b \end{pmatrix}$.

(b)

For part (b), let $\hat{y}_{\text{new}} = \beta_a a_{\text{new}}$, and assume that $\beta_b \neq 0$. **Note that \hat{y}_{new} is formed with β_a , not $\hat{\alpha}$.** Prove that

$$\mathbb{E}[y_{\text{new}} - \hat{y}_{\text{new}}] \neq 0,$$

where the expectation is taken over a_{new} , b_{new} , and ε_{new} . That is, when you exclude b_n from the regression, the predictions evaluated at the limit β_a are biased.

(c)

For part (c), let $\hat{y}'_{\text{new}} = \beta^\top \mathbf{x}_{\text{new}}$. **Note that \hat{y}'_{new} is formed with β , not $\hat{\beta}$.** Prove that

$$\mathbb{E} [y_{\text{new}} - \hat{y}'_{\text{new}}] = 0,$$

where the expectation is taken over a_{new} , b_{new} , and ε_{new} . That is, when you include b_n from the regression, the predictions evaluated at the limit β are unbiased.
